Nandni Vala

Inheritance

1. Single, Multilevel, Multiple, Hierarchical, and Hybrid inheritance in Python.

➤ Inheritance is an object-oriented programming (OOP) concept where a class (child or derived) can inherit attributes and methods from another class (parent or base). Python supports different types of inheritance.

➤ **Single Inheritance**

➤ A child class inherits from a single parent class.

➤ Example:

➤ class Parent:

➤ def display(self):

➤ print("This is the parent class.")

➤ class Child(Parent):

➤ def show(self):

➤ print("This is the child class.")

➤ obj = Child()

➤ obj.display() # Inherited method

➤ obj.show() # Child's own method

➤ **Multilevel Inheritance**

➤ A class inherits from another class, and another class inherits from it (a chain of inheritance).

➤ Example:

➤ `class Grandparent:`

➤ `def show_grandparent(self):`

➤ `print("This is the grandparent class.")`

➤ `class Parent(Grandparent):`

➤ `def show_parent(self):`

➤ `print("This is the parent class.")`

➤ `class Child(Parent):`

➤ `def show_child(self):`

➤ `print("This is the child class.")`

➤ `obj = Child()`

➤ `obj.show_grandparent()` # Inherited from Grandparent

➤ `obj.show_parent()` # Inherited from Parent

➤ `obj.show_child()` # Child's own method

Multiple Inheritance

- A class inherits from more than one parent class.

Example:

```
class Parent1:
```

```
    def display1(self):
```

```
        print("This is Parent1.")
```

```
class Parent2:
```

```
    def display2(self):
```

```
        print("This is Parent2.")
```

```
class Child(Parent1, Parent2):
```

```
    def display_child(self):
```

```
        print("This is the child class.")
```

```
obj = Child()
```

```
obj.display1()      # From Parent1
```

```
obj.display2()      # From Parent2
```

```
obj.display_child() # Child's own method
```

➤ Hierarchical Inheritance

➤ Multiple child classes inherit from the same parent class.

➤ Example:

➤ class Parent:

➤ def show_parent(self):

➤ print("This is the parent class.")

➤ class Child1(Parent):

➤ def show_child1(self):

➤ print("This is Child1.")

➤ class Child2(Parent):

➤ def show_child2(self):

➤ print("This is Child2.")

➤ obj1 = Child1()

➤ obj1.show_parent()

➤ obj1.show_child1()

➤ obj2 = Child2()

➤ obj2.show_parent()

➤ obj2.show_child2()

Hybrid Inheritance

- A combination of two or more types of inheritance.
- Example:
- ```
class Base:
```
- ```
    def show_base(self):
```
- ```
 print("This is the base class.")
```
- ```
class Child1(Base): # Single Inheritance
```
- ```
 def show_child1(self):
```
- ```
        print("This is Child1.")
```
- ```
class Child2(Base): # Hierarchical Inheritance
```
- ```
    def show_child2(self):
```
- ```
 print("This is Child2.")
```
- ```
class Grandchild(Child1, Child2): # Multiple Inheritance
```
- ```
 def show_grandchild(self):
```
- ```
        print("This is the grandchild class.")
```
- ```
obj = Grandchild()
```
- ```
obj.show_base()    # Inherited from Base
```
- ```
obj.show_child1() # Inherited from Child1
```
- ```
obj.show_child2()  # Inherited from Child2
```
- ```
obj.show_grandchild() # Grandchild's own method
```

## 2.Using the `super()` function to access properties of the parent class.

### ➤ **`super()` Function in Python**

- The `super()` function is used to call methods or access properties of a parent class from the child class. It allows you to:
- Reuse the functionality of the parent class without explicitly naming it.
- Make code maintainable by avoiding hardcoding the parent class name.

### ➤ **Syntax**

- `super().method_name(args)`

### ➤ **Key Use Cases of `super()`**

#### ➤ **Accessing Parent Class Methods**

#### ➤ **Accessing Parent Class Constructor (`__init__`)**

#### ➤ **Avoiding Redundancy in Multiple Inheritance**

#### ➤ **Accessing Parent Class Methods**

- Using `super()` to call a method in the parent class.

➤ Example:

➤ class Parent:

➤ def greet(self):

➤ print("Hello from Parent.")

➤ class Child(Parent):

➤ def greet(self):

➤ super().greet() # Call the parent class method

➤ print("Hello from Child.")

➤ obj = Child()

➤ obj.greet()

➤ Output:

➤ Hello from Parent.

➤ Hello from Child.

## ➤ Accessing Parent Class Constructor

➤ Using `super()` to invoke the parent class's `__init__` method.

➤ Example:

➤ `class Parent:`

➤     `def __init__(self, name):`

➤         `self.name = name`

➤         `print(f"Parent initialized with name: {self.name}")`

➤ `class Child(Parent):`

➤     `def __init__(self, name, age):`

➤         `super().__init__(name) # Call parent class constructor`

➤         `self.age = age`

➤         `print(f"Child initialized with age: {self.age}")`

➤ `obj = Child("John", 12)`

➤ Output:

➤ Parent initialized with name: John

➤ Child initialized with age: 12

## Using super() in Multiple Inheritance

In multiple inheritance, super() ensures that the **Method Resolution Order (MRO)** is followed.

Example:

```
class A:
 def display(self):
 print("Class A")

class B(A):
 def display(self):
 super().display()
 print("Class B")

class C(B):
 def display(self):
 super().display()
 print("Class C")

obj = C()
obj.display()
```
